# Refractive Index of Silicon and Germanium and Its Wavelength and Temperature Derivatives

H. H. Li

Center for Information and Numerical Data Analysis and Synthesis, Purdue University, West Lafayette, Indiana 47906

Refractive index data for silicon and germanium were searched, compiled, and analyzed. Recommended values of refractive index for the transparent spectral region were generated in the ranges 1.2 to 14  $\mu$ m and 100–750 K for silicon, and 1.9 to 16  $\mu$ m and 100–550 K for germanium. Generation of these values was based on a dispersion equation which best fits selected data sets covering wide temperature and wavelength ranges. Temperature derivative of refractive index was simply calculated from the first derivative of the equation with respect to temperature. The results are in concordance with the existing dn/dT data.

Key words: Germanium; optical constants; refractive index; silicon; temperature coefficient of refractive index.

#### 1. Introduction

The refractive index of a material is one of its fundamental and useful optical properties. Accurate knowledge of the refractive index over a wide range of wavelength is indispensable for many applications. Although this property continues to receive attention for both industrial as well as purely scientific applications, the current state of the available data for certain widely used materials is less than adequate. While experimental results for the refractive index of pure silicon and germanium are reported by several groups of investigators claiming high internal accuracy and agreement, the data as a whole are in disagreement.

In this study, an attempt is made to consolidate all of the published refractive index data on silicon and germanium and to critically evaluate the raw experimental data and techniques of observation. A modified Sellmeier type dispersion relation is utilized to describe the available body of data. The resultant equations were used to generate the most probable values which agree with the selected experimental data to within  $\pm 2.0 \times 10^{-3}$  over the wavelength range 1.2 to 14.0  $\mu m$  for silicon and 1.9 to 18.0  $\mu m$  for germanium.

## 2. Theoretical Background on Refractive Dispersion in Crystals

Dispersion relations are of fundamental importance to the description of the optical properties of materials. They relate both the absorptive and dispersive properties into one relatively concise statement describing a general linear relationship between fundamental amplitudes. The only two major restrictions are boundedness and causality, thus these relations are useful in many fields and applications in both physics and engineering.

The dispersion of radiation in an optical material is intimately related to the microscopic structure of the material itself. In the most general terms, long wavelength transmission of a pure crystal is limited by molecular vibrations, rotations while short wavelength transmission is limited by the electronic excitations of individual atoms. Practically, this implies that the fundamental transparent spectral range may be determined by knowledge of the absorption spectra of a

material. The energy necessary for electronic excitations is generally noted by the location of the energy gaps whicle the molecular excitation is represented by the fundamental phonon frequency. Experimentally, both of these parameters may be altered by various techniques including doping, stress, strain, and temperature variations. One other area of primary importance is that of point defects. The varied effects of point defects in semiconducting materials plays an important role in both the electrical and optical properties, however a detailed analysis of these effects is beyond the scope of this work. A more complete analysis of these effects is given by Crawford and Slifkin [1].

In general, the absorption and transmission of a material is not well known except for a small wavelength range. Thus, on theoretical grounds, it is convenient to consider dispersion as arising from two major sources separately; namely, the bound and free electrons. In non-conducting dielectric materials, the bound electron, or molecular, interactions tend to predominate, while free electron interactions are most common in metals. In semiconducting materials, both of these contributions may be important. In fact, most semiconductors show an optical absorption and an anomalous dispersion in the far-infrared region. This effect is rather small in covalent semiconductors like Si and Ge, it increases, however, with increasing polarity. Both the radio-frequency measurement and infrared observation indicate that the effect of free carriers on Si and Ge are negligibly small. Furthermore, in the elemental Si and Ge, the lattice has no permanent dipole moment and consequently the lattice absorption is small.

For pure dielectrics, the wavelength or frequency dependence of the optical constants may be described by the classical treatment of Lorentz. The theory assumes the solid to be composed of a series of independent oscillators, which are set into forced vibrations by the incident radiation. The Lorentz theory of absorption and dispersion for both insulating and semi-conducting materials leads to the two familiar relations,

$$n^{2} - \kappa^{2} = 1 + \sum_{i} \frac{N_{i}(\nu_{i}^{2} - \nu^{2})}{(\nu_{i}^{2} - \nu^{2})^{2} + \gamma_{i}^{2} \nu^{2}}$$
(1)

and

$$2n\kappa = \frac{1}{\nu} \sum_{i} \frac{N_{i} \gamma^{2} \nu^{2}}{(\nu_{i}^{2} - \nu^{2})^{2} + \gamma_{i}^{2} \nu^{2}},$$
 (2)

where n is the refractive index,  $\kappa$  the absorption index,  $N_i$  the parameter associated with the oscillator strength of the *i*-th oscillator,  $\nu_i$  the resonant frequency of the *i*-th oscillator and  $\gamma_i$  the damping constant of the *i*-th oscillator. In the transparent wavelength region, eq (1) can be reduced to a Sellmeier type equation by neglecting the line width of the oscillators, thus reducing to:

$$n^{2} = 1 + \sum_{i} \frac{a_{i} \lambda^{2}}{\lambda^{2} - \lambda_{i}^{2}} + \sum_{f} \frac{b_{f} \lambda^{2}}{\lambda^{2} - \lambda_{f}^{2}}.$$
 (3)

Terms in the first summation are contributions from the ultraviolet absorption bands and those in the second from the infrared absorption bands. From eq (3), the dielectric constants,  $\epsilon_{\infty}$  and  $\epsilon_{0}$ , of the material under consideration are defined as:

$$\epsilon_{\infty} = 1 + \sum_{i} a_{i},$$
 and (4)

$$\epsilon_0 = 1 + \sum_i a_i + \sum_j b_j$$

As noted before, the effects of free carries and lattice absorption are found to be negligibly small in elemental Si and Ge, thus the contributions from infrared absorption bands can be dropped and eqs (3) and (4) are simplified to:

$$n^2 = 1 + \sum_{i} \frac{a_i \lambda^2}{\lambda^2 - \lambda^2} \tag{5}$$

and

$$\epsilon = \epsilon_0 = \epsilon_{\infty} = 1 + \sum_i a_i. \tag{6}$$

In an ideal application of eq (5), one would need to know the wavelengths of all of the absorption peaks in the short wavelength region. This is very difficult in practice because of the large number of absorption peaks. In fact, only a few absorption peaks are accessible for experimental observation. It is also observed that among the absorption peaks, only the one that is located closest to the transparent region has noticeable effect on the refractive index in the transparent region. In order to simplify the calculations of the effect due to unobserved absorption bands and those other than the one affecting most the refractive index in the transparent region, the following considerations were taken. Each term, except the predominating one, in the summation of eq (5) is expanded as:

$$\frac{a_t \lambda^2}{\lambda^2 - \lambda_t^2} = a_t \left( 1 + \frac{\lambda_t^2}{\lambda^2} + \frac{\lambda_t^4}{\lambda^4} + \cdots \right)$$
 (7)

Since  $\lambda_i$ 's are usually considerably smaller than  $\lambda$ 's in the transparent region, a good approximation of eq (5) is

$$n^{2} = 1 + \sum_{i=0}^{N} a_{i} \left( 1 + \frac{\lambda_{i}^{2}}{\lambda^{2}} \right) + \frac{a_{1}\lambda^{2}}{\lambda^{2} - \lambda_{i}^{2}}$$
 (8)

01

$$n^{2} = 1 + \sum_{i} a_{i} + \frac{1}{\lambda^{2}} \sum_{i=2}^{N} a_{i} \lambda_{i}^{2} + \frac{a_{1} \lambda_{1}^{2}}{\lambda^{2} - \lambda_{1}^{2}}, \tag{9}$$

with  $a_1$  and  $\lambda_1$  associated with the term that has the greatest effect on the refractive index in the transparent region. Therefore, we have the simplified dispersion equation as:

$$n^2 = \epsilon + \frac{A}{\lambda^2} + \frac{B \lambda_1^2}{\lambda^2 - \lambda_1^2}, \tag{10}$$

where A and B are adjustable parameters,  $\lambda_1 = 1.1071$  µm for Si and  $\lambda_1 = 1.8703$  µm for Ge [2]. Equation (10) can be generalized to include temperature as an inpendent variable. In this case, the parameters  $\epsilon$ , A, B, and  $\lambda_1$  are functions of temperature.

At long wavelengths, the dielectric constant,  $\epsilon$ , is equal to the square of refractive index, i.e.,  $\epsilon(T) = n^2(T)$  at long wavelength. Therefore,

$$\frac{1}{\epsilon(T)} \frac{d\epsilon(T)}{dT} = 2 \frac{1}{n(T)} \frac{dn(T)}{dT}.$$
 (11)

Cardona, Paul, and Brooks [3] found the longwavelength (1/n)(dn/dT) to be  $(3.9 \pm 0.4) \times 10^{-5} \text{K}^{-1}$ for Si and  $(6.9\pm0.4)\times10^{-5}\mathrm{K}^{-1}$  for Ge, between 77 and 400 K. Higher values of (1/n)(dn/T) were observed by other workers:  $(4.8\pm0.2)\times10^{-5}K^{-1}$  for silicon [4] and  $9.7 \times 10^{-5} \text{K}^{-1}$  for germanium [5]. However, these constant values of (1/n)(dn/dT) only hold at high temperatures. Deviation from linearity at low temperatures requires that a non-linear relation between  $\epsilon$  and T be established. The values of the dielectric constant which appear in the literature are inaccurate. In the survey work of Young and Frederikse [6], the value for Si varies from 11.7 to 12.1 and that of Ge from 13.6 to 16.6. As a consequence, the reported values of  $\epsilon$  are not suitable for eq (10) and  $\epsilon(T)$  can only be obtained by fitting selected room-temperature refractive index data to eq (10). The temperature dependence of  $\lambda_1$  was investigated by Macfarlane et al. [7, 8], their results are  $d\lambda_1/dT = 0.000267 \ \mu \text{m} \ \text{K}^{-1}$  for Si and 0.001016  $\mu m$  K<sup>-1</sup> for Ge at temperatures higher than 200 K. Non-linearity predominates at low temperatures.

The parameters, A and B, in eq (10) can be expressed in terms of temperature based on the considerations given below. Since

$$A = \sum_{i=2}^{N} a_i \lambda_i^2 \text{ and } B = a_1$$
 (12)

and the a's are respectively proportional to the density of the corresponding oscillator, the temperature dependence of  $a_i$  is given by the relation

$$\frac{1}{a_i}\frac{da_i}{dT} = -\frac{1}{V}\frac{dV}{dT} = -3\alpha, \tag{13}$$

where V and  $\alpha$  are respectively the volume and the thermal expansion coefficient of the material. Hence

$$a_1 = a_{10} e^{-3 \int_{293}^{T} \alpha \, dT} = a_{10} e^{-3\Delta L(T)/L_{293}},$$
 (14)

with  $a_{0t}$  being the value of  $a_t$  at 293 K. Furthermore, each of the  $\lambda_t^{2}$ 's in the summation can be considered as a quadratic function of temperature because it is an experimentally observed fact that  $\lambda_t$  is approximately a linear function of T [9] in the temperature region of interest. Therefore

 $A(T) = e^{-3\Delta L(T)/L_{293}} (A_0 + A_1 T + A_2 \dot{A}^{2})$  (15)

and

$$B = B_0 e^{-3\Delta L(T)/L_{293}}, \tag{16}$$

where  $A_0$ ,  $A_1$ ,  $A_2$ , and  $B_0$  are adjustable deficients. Incorporating these considerations into equal to the latter can be written in the general form as

$$n^2 = f(\lambda, T). \tag{17}$$

In the actual cases, however, one finds negligibly small values for  $B_0$ 's through data fitting procedures. As a result, the following dispersion equation is adopted to calculate the refractive index of Si and Ge:

$$n^2(\lambda, T) = \epsilon(T) + \frac{A(T)}{\lambda^2}$$
 (18)

With  $\epsilon$  and the parameters  $A_0$ ,  $A_1$ , and  $A_2$  appropriately determined, dn/dT and  $dn/d\lambda$  can be easily calculated taking the first derivatives of eq (18) with respect to T and  $\lambda$ .

### 3. Presentation of Numerical Data

Reference data are generated here through pritical evaluation, analysis, and synthesis of the available experimental data. The procedure involves ritical evaluation of the validity and accuracy of the available data and information, resolution, and reconciliation of disagreements in cases of conflicting data, correlation of data in terms of various controlling parameters, curve fitting with theoretical or empirical equations, and comparisons of experimental values with predictions. No attempt was made to analyze the thinfilm data and the regions of strong absorption, because of the scantiness of reliable information. However, experimental data of thin films and absorption regions are also presented along with those of the transparent region in the tables reporting experimental data.

A number of figures and tables summarize the information and give data as a function of wavelength and temperature. The conventions used in this presentation, and specific comments concerning the interpretation and use of the data are given below. The subsections for Si and Ge give all the information and data for a given material and cover the following:

- a. A text discussing the data, analysis, and recommentations,
- b. A figure of experimental n values (for wavelength and temperature, respectively),
  - c. A figure of experimental  $dn/dT = f(\lambda)$ ,
  - d. A figure of experimental dn/dT = f(T),
- e. A table of experimental data on  $n=f(\lambda)$ , given in Appendix,
- f. A table of experimental data on n=f(T), given in Appendix,
- g. A table of experimental data on  $dn/dT=f(\lambda)$  given in Appendix,
- h. A table of experimental data on dn/dT = f(T) given in Appendix,

J. Phys. Chem. Ref. Data, Vol. 9, Na. 3, 1980

- i. Figures of recommended or provisional values of n, dn/dT, and  $dn/d\lambda$ ,
- j. Tables of recommended or provisional values of n, dn/dT, and  $dn/d\lambda$ .

In figures containing experimental data, selected data sets are labeled by appropriate legends corresponding to those in the corresponding tables of experimental data given in Appendix, where specifications for individual data sets are also included.

There are a number of experimental methods used for the determination of refractive index, among which the following are those commonly used:

Deviation method (prism method)
Interference method
Transmission method
Reflection method
High frequency modulation method
Brewster angle method
Polarization method
Thickness determination method
Multilayer method

The methods listed above are arranged in the order of their inherent accuracy or popularity. The deviation method is the most popular means of determining the refractive indices, but the accuracy of the results depends on the conditions of the prism specimen. The highest accuracy that can be attained is in the fifth decimal place. The interference technique can be used to obtain data up to the fourth decimal place. Transmission and reflection methods yield results good to the second place, while the multilayer results are no better than two places. For a comprehensive, yet concise, review of all these methods, the reader is referred to references [10] and [11].

Dispersion equations for Si and Ge have been proposed in earlier works. Available relations are discussed in the text so as to facilitate comparison. Refractive indices for most of selected data sets are reported to the fourth decimal place. However, detailed compositions and characterizations of the specimens were usually not clearly given. Since impurities in the sample and conditions of the surface are decisive factors affecting the accuracy of the observed results, such highly precise data cannot be applied to a sample chosen at random. For this reason no attempt is made to recommend any particular set of data with the reported high accuracy, but to generate the most probable values for the pure crystals. As a result, the estimated uncertainties for the recommended values on the refractive index are higher than those for the reported data obtained even by highprecision measurements. The accuracy of the recommended refractive index values in this work is estimated to be 1 to  $2\times10^{-3}$ .

### 3.1. Silicon, Si

There are 55 sets of experimental data available for the refractive index (wavelength dependence and temperature dependence) of silicon as tabulated in tables A–1 and A–2 and plotted in figures I and 2. It should be pointed out that a few of the data sets are from observations for thin films and are reported here for purposes of comparison. After careful review and evaluation of the available information, it was found that data sets reported by Briggs [12], Salzberg and Villa [13], Cardona et al. [3], Lukes [4, 14], Primak [15], and Icenogle et al. [5] are representative for the refractive index of silicon in the transparent region between 1.3 and 12  $\mu$ m.

Briggs [12] probably was the first one who reported the measured refractive index of silicon. A 99.8% pure silicon wedge specimen of about 11.5° apex angle was investigated using minimum deviation method over a spectral range from 1.05 to 2.60  $\mu$ m. He stated that the accuracy of his measurements was good to the second decimal place.

Since this first measurement, a number of other investigations have been made. Refractive index determination from 1.35 to 11.04  $\mu$ m was made by Salzberg and Villa [13] for a wedge specimen of about 16° apex angle. The sample, of unknown purity, was obtained from the Texas Instrument Company. The autocollimation minimum deviation method was used to determine the refractive index. Their results were lower than those of Briggs by about 5 parts in the third decimal place. They claimed an accuracy of  $\pm 2$  parts in the fourth decimal place.

Cardona et al. [14] measured the refractive index of a thin silicon wedge of  $5^{\circ}$  in the wavelength range from 1 to 5  $\mu$ m and at temperatures 100, 194, and 297 K. Their results were about 4 parts in the third decimal place lower than the corresponding ones of Briggs.

Lukes [4, 14] measured the refractive index at five wavelengths, 1.259, 1.407, 1.564, 2.409, and 5.156  $\mu$ m, over a wide temperature region between 109 and 750 K by the conventional method of minimum deviation. The silicon wedge of  $\sim$ 18° angle was prepared from a p-type single crystal with a resistivity of  $\sim$ 380 ohm-cm. The reported error was  $\pm \sim$ 0.0004, but his values of refractive index were systematically lower than those of Salzberg and Villa by 0.0015.

Primak [15] went to great lengths in the determination of the refractive index of silicon from 1.12 to 2.16  $\mu$ m. His results corresponded closely to those reported by Lukes. As he took into account all of the influencing factors in arriving at the final values, he believed that his values were reliable within an uncertainty of 1 or 2 parts in the third decimal place.

Icenogle et al. [15] made a thorough investigation on the refractive index for silicon over the temperature and wavelength ranges of 99–296 K and 2.554–10.27  $\mu$ m, respectively. The samples were obtained from the Exotic Materials, Inc. and were characterized as "good optical grade" without further details of purity of the material. The results are in fair agreement with other data sets. The claimed errors were  $\pm 3 \times 10^{-4}$ .

For the purpose of ease of comparison, the above mentioned data sets are replotted in figure 3. It is obvious that the disagreement among the values reported by different researchers is greater than the accuracy claimed by them. Although internal consistency was observed in each investigation, unaccounted sources of errors are responsible for these discrepancies.

Primak [15] devoted considerable space to the discussion of both systematic and random errors with the conclusion that the systematic errors played the key role in data discord. The possible sources of error were attributed to:

- i. Inadequate care in checking the pyramidal error. If the wedge angle was not perpendicular to the circle and parallel to the telescope, the effective angle would be greater than the true wedge angle with the consequence of a larger deviation angle which would lead to a larger value of refractive index.
- ii. Small wedge angle of the samples. For a highly refracting material such as silicon, a small wedge angle is required to measure the refractive index. As a result, large errors in angle measurement can be introduced and hence in the observed refractive index.
- iii. Broad detector used. Observation in the infrared requires a detector in the determination of deviation angle. The detectors that have been used are in general many times broader than the width of the spectral line, thus decreasing the accuracy in reading the angles. Significant errors are, therefore, inevitably introduced.
- iv. Optical inhomogeneity of the sample. Optical inhomogeneity of the material causes image distortion and thus the error in the angle setting.

Among the above sources, the smallness of the wedge angle is the major factor that contributes to the error. A combination of these contributions limits the accuracy of the measurement of the refractive index by the minimum deviation method to 1 or 2 units in the third decimal place, a few times higher than that claimed by most investigators.

The effect of impurities on the refractive index is considerable. In some cases, observations made on samples of questionable origin and undefined purity may yield radically different results. Villa [16] reported his grossly divergent values (shown in figure 3) to show that sample differences can be very significant. In figure 1 one can see Simon's [17] radically different results obtained for a silicon sample of high impurity content. The data of Spitzer et al. [18], obtained on heavily doped silicon, are significantly divergent from those of pure samples. Thus, when the effects of impurities are taken into consideration, discrepancies from pure samples may be much larger than 2 parts in the third decimal place.

Although the factors discussed above are well known, unfortunately they are generally not cited in literature, but must be deduced from the assigned accuracies. In the present work it is assumed that data sets that are discordant only in the third decimal

place are in reasonable agreement. This assumption can be supported by a careful comparison of the observations by Icenogle et al. [5] in which the values of the refractive index at a given wavelength and temperature, obtained from wavelength-dependence observation and from temperature-dependence observation, can be different in many cases by more than ! part in the third decimal, few times higher than the claimed precision of  $\pm 3 \times 10^{-4}$ .

More data can be found in references [19-30] and are given in tables A-1 and A-2, in which one can find also data sets obtained on thin films. No attempt was made to analyze the thin film data. However, it has been observed that the refractive indices of pure silicon thin films tend to agree with those of bulk crystal if the films are deposited on substrates maintained at elevated temperatures during deposition or appropriately annealed after deposition. Surface contamination appears to be the most serious problem. However, data for thin films reported by those who exercise appropriate precautions in the sample preparation are usually in agreement with those of bulk material.

literature data on the temperature coefficient of the refractive index is rather scarce. Data reported in tables A-3 and A-4 and plotted in figures 4 and 5 are those of Lukes [4, 14]. His values were evaluated from his measurements given in table A-2 and in figure 2.

A though a significant body of data on the refractive index of silicon is available, an attempt to analyze data has been rare. In the literature, only one quantitative study has been proposed. Hertzberger and Salzberg [31] proposed a dispersion equation for silicon which was derived in conjunction with 13 other materials. They noted that a comparison of the data from 14 materials indicated that all had refractive index values varying asymptotically with  $\lambda^2$ . Furthermore, the mean asymptote was found to be at  $\lambda_0$ = 0.168 um. The dispersion relation was based upon a Taylo: expansion in  $\lambda^2$  which retains only the linear terms. The equation is

$$n = A + BL + CL^2 + D\lambda^2 + E\lambda^4, \tag{19}$$

where  $\lambda$  is in units of  $\mu$ m,  $L=1/(\lambda^2-\lambda_0^2)$ , and the coefficients for silicon in the region 1.3 to 11.0  $\mu$ m are

$$A=3.41696, \qquad D=-0.0000209, \\ B=0.138497, \qquad E=0.000000148. \\ C=0.013924.$$

The determination of the coefficients in this equation was based on a single data set by Salzberg and Villa [13] and the fit is excellent.

In the present work, eq (10) is used to represent the refractive index for silicon. The main task was the selection of the appropriate parameters  $\epsilon$  and  $\lambda_i$ , and the determination of the coefficients A and B. But the most important of all was the selection of reliable data sets used as input information to eq (10). The selected data were limited to the works of Salzberg and Villa, Primak, and Icenogle et al. Data from Cardona et al.

and Lukes were not used on the basis that their values had to be read off from the graphs in their reports. Deviations between the graph readings and the true values can occur in the second decimal place of the data. The data of Briggs were not chosen as his values disagree in the second decimal place with the corresponding values of Primak who exercised great care in the experiment for high purity silicon specimens. The remaining data sets from Primak, Salzberg and Villa, and Icenogle et al. constitute the basis of our recommendations. Their results are in agreement in the third decimal as expected. Fortunately, Icenogle's work covered a sizable temperature range, thus permitting the prediction of the refraction index at temperatures other than room temperature.

Selection of  $\epsilon$  and  $\lambda_1$  in eq (10) was rather difficult. Figure 6 shows the results of Cardona et al. [3] who observed the relative changes of refractive index,  $\Delta n/n$ , at a wavelength of 3 µm as temperature varied between 77 to 400 K. The average slope, (1/n)(dn/dT), of this curve is  $(3.9 \pm 0.4) \times 10^{-5} \text{K}^{-1}$ . Lukes [4, 14] obtained a higher value of  $4.8\pm0.2\times10^{-5}\mathrm{K^{-1}}$  for (1/n)(dn/dT) by extrapolating his results to longer wavelengths. It appeared that at long wavelengths,  $\epsilon$  in eq (10) could be determined from the relation  $(1/\epsilon)(d\epsilon/dT) = (2/n)(dn/dT)$  using one of the above mentioned (1/n)(dn/dT) values. The result should be an exponential relation of the form  $\epsilon = \epsilon_0 e^{\epsilon T}$ . However, es the constancy of (1/n)(dn/dT) does not hold for the wide termperature range of our interest, an empirical relation between  $\epsilon$  and T had to be found based on the experimental data on n.

It is shown in figure 2 that curves of temperature dependence of refractive index at various wavelengths are essentially parallel to each other and that each of them smoothly and monotonically increases with temperature. This provides the possibility to find relations between  $\epsilon$  and T. Since  $\epsilon$  is nearly equal to  $n^2$ at long wavelengths, the best choice in the present case seemed to be the refractive indices at 10.27 µm by Icenogle et al. [5]. As the available data of n(T) at 10.27 µm cover only the limited temperature range from 100 to 298 K, a wider temperature range coverage is needed to establish the relation between e and T that is valid over the temperature range 100-750 K. As shown in figure 2, the 5.156 µm curve by Lukes [14] is slightly above, but parallel to, the extension made from the 10.17  $\mu$ m curve. The required 10.27  $\mu$ m data in the high temperature region can be estimated by an appropriate extrapolation of Icenogle's data within that region. In this way, the following polynomial expression is found to be valid at 10.27 µm ond aver 100-750 K temperature range,

$$n^{2}(10.27 \ \mu m, T) = 11.4552 + 2.7765 \times 10^{-4}T + 1.7066 \times 10^{-6}T^{2} - 8.1423 \times 10^{-10}T^{3}.$$
 (20)

Since at long wavelengths the dielectric constant closely approaches  $n^2$ , it is acceptable to consider the

above quantity as a proportional factor and thus express the dielectric constant by the relation

$$\epsilon(T) = En^2(10.27\mu m, T),$$
 (21)

where E is the proportional constant.

The spectral positions of resonant absorption peaks have been observed by a number of investigators. Moss [32] made an attempt to calculate the refractive indices in the transparent region from the absorption data based on the general principle of oscillatory system. The spectral position of the natural frequency in his single oscillator model was determined at 3.4 eV or  $\lambda = 0.365 \ \mu m$ . McLean [2] investigated the absorption edge spectrum of silicon and found the optical energy gap at 300 K to be  $E_g=1.12$  eV or  $\lambda_1=1.1071$   $\mu m$ . Macfarlane et al. [7] further studied the absorption edge spectrum and found that the temperature variation of the optical energy gap is essentially linear in the temperature region 250-480 K, but nonlinearity progressively predominates at lower temperatures, as seen from figure 7. Lukes and Schmidt [9] studied the reflectivity spectrum of silicon and found two additional absorption peaks at about 0.36 and 0.27  $\mu$ m. The first one is in line with the Moss' [32] result, while the second corresponds to the prediction of Yu and Cardona [33]. A summary of these findings results in three absorption peaks; namely:  $\lambda_1 = 1.1071 \mu m$ ,  $\lambda_2 = 0.365 \mu m$ , and  $\lambda_8 = 0.27 \mu m$ , that supposedly have significant effects on the refractive index in the transparent region from 1.2 to 14  $\mu$ m.

An attempt was made to fit the selected data to an equation similar to eq (10) by including extra terms due to  $\lambda_2$  and  $\lambda_3$ . It was found, however, that the introduction of the  $\lambda_2$  aand  $\lambda_3$  terms did not improve the agreement obtained when only the  $\lambda_1$  term was included. Furthermore, the coefficients of the  $\lambda_2$  and  $\lambda_3$  terms could not be uniquely defined because there were no reliable data in the regions bounded by and near the three peak wavelengths. Also, the value of B was found to be negligibly small, thus making the contribution of the last term in eq (10) insignificant. As a consequence, eq (18) was adopted and the least squares fitting of selected data to this equation yielded the following expression for the refractive index of silicon in the ranges 1.2 to 14  $\mu$ m and 100-750 K:

$$n^{2}(\lambda, T) = \epsilon(T) + \frac{L(T)}{\lambda^{2}} (A_{0} + A_{1}T + A_{2}T^{2}),$$
 (22)

where

$$\epsilon(T) = 11.4445 + 2.7739 \times 10^{-4} T + 1.7050 \times 10^{-6} T^2 - 8.1347 \times 10^{-10} T^3,$$
 $L(T) = e^{-3\Delta L \cdot T^2} / L_{293},$ 
 $\lambda = \text{wavelength in units of } \mu \text{m},$ 
 $T = \text{temperature in units of } K,$ 
 $A_0 = 0.8948,$ 
 $A_1 = 4.3977 \times 10^{-4},$ 
 $A_2 = 7.3835 \times 10^{-8},$ 

568 H. H. LI

and from reference [34]

$$\begin{array}{c} \frac{\Delta L\left(T\right)}{L_{\rm 298}} \!\!=\! -0.021 \!-\! 4.149 \! \times \! 10^{-7} T \!\!-\! 4.620 \\ \times \! 10^{-10} \, T^{\rm z} \!\!+\! 1.482 \! \times \! 10^{-11} \, T^{\rm z} \!\!\!\! & (20 \!\!-\! 293 \; \rm K) \end{array}$$

It should be pointed out that the room-temperature dielectric constant for silicon can be calculated from the expression for  $\epsilon$  in eq (22). The result is 11.66 which agrees well with the commonly accepted value of 11.7.

Equation (22) was used to calculate the recommended values of the refractive index of silicon with uncertainties of  $\pm 2 \times 10^{-3}$ . The recommended values are given in table 1 and plotted in figure 8. To provide visual comparison of calculated values with the experimental data, calculated values at a few specified temperatures and wavelengths are plotted in figures 2 and 3 where excellent agreement is revealed. Tables 2 and 3, respectively, give the calculated dn/dT and  $dn/d\lambda$  values based on the first derivatives of eq (22) with respect to T and  $\lambda$ . The corresponding plots are shown in figures 9 and 10.

Uncertainties in the calculated dn/dT are estimated based on Icenogle's [5] results which were the essential data on which eq (22) is based. Icenogle et al. evaluated  $\Delta n/\Delta T$  values using their own measurements of n and found the average accuracy in  $\Delta n/\Delta T$  to be about  $\pm 0.15 \times 10^{-4} \, \mathrm{K}^{-1}$ . Error bars corresponding to this amount are drawn on the calculated curves in figures 4 and 5 where calculations are compared with the experimental data. Although accuracies of experi-

mental dn/dT are not given in Lukes' work [4, 14], it is reasonable to adopt the ame experimental error bar since the n versus T curves in figure 2 are closely parallel.

Uncertainties of the calculated  $dn/d\lambda$  are estimated in the following manner. Taking the first derivative of eq (22) with respect to  $\lambda$ , where

$$-dn/d\lambda = (1/n)A(T)/\lambda^3 = (1/n\lambda)(n^2 - \epsilon), \qquad (23)$$

which leads to

$$\delta(dn/d\lambda) \simeq \frac{1}{2} 2\delta n/\lambda.$$
 (24)

Based on the fact that the spectral dependence of the refractive index from various investigators are essentially parallel, it should be permissible to apply the uncertainties,  $\delta n = \pm 3 \times 10^{-4}$ , quoted in Icenogle's work to evaluate  $\delta (dn/d\lambda)$  using the above relation for the wavelength region between 2.55 and 14  $\mu$ m. For wavelengths <2.55  $\mu$ m, the uncertainty  $\delta n = \pm 2 \times 10^{-3}$  of eq (22) should be used. Under these conditions, uncertainties of  $dn/d\lambda$  are about  $\pm \frac{10}{2} \times 10^{-4} \mu$ m<sup>-1</sup> at 2  $\mu$ m,  $\pm 2.4 \times 10^{-4} \mu$ m<sup>-1</sup> at 2.55  $\mu$ m,  $\pm 0.6 \times 10^{-4} \mu$ m<sup>-1</sup> at  $\pm 0.44 \times 10^{-4} \mu$ m<sup>-1</sup> at  $\pm 0.44$ 

It should be noted that calculated values in tables 1, 2, and 3 are given with more digits than warranted merely for the purpose of tabular smoothness. As these values are calculated from an equation, it is highly desirable to give enough digits to show the variation of the variables in the equation and to provide comparison among neighboring entries. These extra digits which are insignificant and not in dicative of the accuracy of the values are indicated with an overstrike. Appropriate uncertainties in the recommended values discussed in the text are quoted in the footnotes of the tables.

### 3.2. Germanium, Ge

582

There are 88 sets of experimental data available for the refractive index (wavelength and temperature dependences) of germanium as given in tables A-5 and A-6 and plotted in figures 11 and 12. A few sets of measurements on thin films are included for the purpose of complet mess and comparision. After careful review and evaluation of the available information, it was found that the data reported by Brigge [12], Salzberg and Villa [13], Cardona et al. [3], Rank et al. [35], Lukes [36, 37], Icenogle et al. [5], and Edwin et al. [38] are representatives for the refractive index of germanium in the transparent region between 1.8 and 16 µm.

Briggs [12] measured the refractive index of a germanium specimen of 99.99% purity over the spectral region between 1.8 and 2.6 µm. He used the minimum deviation method on a wedge of about 17° apex angle. The range of his measurements was limited on the short wavelength side by absorption in the prism, and on the long wavelength side by absorption in the glass components of the optical system used. The claimed error was a few parts in the third decimal place. He also observed a definite increase in refractive index value with increasing temperature. In other words, the temperature coefficient of refractive index of germanium is positive.

Since Briggs' observation, several other independent measurements were carried out. Salzberg and Villa [13] used the autocollination minimum deviation method in the determination of n over a wide wavelength range from 2.0 to 16  $\mu$ m for a single crystal germanium priem of 11.8 apex angle with unknown purity. The reported accuracy was estimated to be  $\pm 2$  parts in the fourth decimal. Compared with the results of Briggs, their n values are systematically about 0.005 lower in the corresponding spectral region. No source was ascribed for such discrepancies. In a later work [39], a polycrystalline sample was measured and they found that there were no significant differences between the results obtained for different crystals.

Cardona et al. [3] measured the refractive index for a thin germanium wedge of 5° in the wavelength range from 1.7 to 5.6 µm and at temperatures 87. 190, and 297 K. Their n values were also about 0.005 lower than those of Briggs in the corresponding wavelength region. Their results clearly indicate that dn/dt of germanium is positive over the transparent wavelength region. At a fixed long wavelength, 3  $\mu$ m, they measured the relative changes of n,  $\Delta n/n$ , as a function of temperature. A linear relation between  $\Delta n/n$  and T was observed over the temperature range between 77 and 400 K. The result, (1/n)(dn/dT) $=(6.9\pm0.4)\times10^{-5}\mathrm{K}^{-1}$ , agrees well with those for the dielectric constant measurement at 10 mc/s [40] at low temperatures, but discrepancies occurred at high temperatures where values obtained in reference [40] are higher. Such discrepancies were attributed to the inhomogeneities and impurities in the samples which effectively reduced the thickness of the capacitors and thus resulted in an apparent increase in the dielectric constant.

Rank et al. [35] measured the refractive index over a wavelength region between 2.0 and 2.4  $\mu$ m by an interferometric method. A single crystal germanium of unspecified purity was used and the resulting n's were about 0.01 higher than the corresponding values of Briggs. The temperature variation of the refractive index was observed to have a positive coefficient and the absorption edge moved to longer wavelengths as temperature increased.

Lukes [36, 37] measured the refractive index for several germanium prism samples cut from single crystals of varying impurity. His measurements were carried out over a wavelength range of 1.8–5.5  $\mu$ m and the temperature range 100–530 K. The results obtained for the purest sample were in agreement with those of Salzberg and Villa, while the results for the impure samples showed discrepancies at the long wavelengthe, the higher the impurity, the lower the n. In the shorter wavelength region,  $<4~\mu$ m, the refractive index appeared practically independent on the impurity content.

Icenogle et al. [5] made a thorough investigation on the refractive index for germanium over the 95–297 K and 2.554–12.360  $\mu m$  regions. The samples were obtained from the Exotic Material, Inc. and were characterized as "good optical grade" without further details of purity of the material. The claimed error in the measurement of n was  $+6\times10^{-4}$ . The results disagree with those of other workers by several parts in the third decimal. At room temperature and in the wavelength region where  $\lambda>3~\mu m$ , Icenogle's values are higher than the earlier works. The sources for such discrepancies can possibly be ascribed to differences in the impurity content of the samples.

Edwin et al. [38] made careful measurements of n for well characterized germanium specimens in the spectral region 8-14  $\mu$ m. Their results are in agreement with Icenogle's values when account is taken of both of their claimed uncertainties. Edwin et al. took into account the main sources of uncertainty in arriving at their reported values, including probable errors from temperature readings, angle determinations, wavelength identification, curvature of slit image, and random errors. The claimed uncertainty of their results is  $\pm 0.0003$ . According to their sample description, the specimens had a resistivity about 45 to 53 ohm-cm which indicated that they used purer samples than others.

For ease of comparison, the above mentioned data sets are replotted on an enlarged scale in figure 13. It is obvious that the disagreement among the data sets is greater than the individually claimed accuracies.

True internal consistency was observed in each measurement, unaccounted sources or errors were responsible for the discrepancies.

Primak [15] devoted considerable space to discussions of both systematic and random errors for the case of silicon (see subsection 3.1). The conclusions are generally valid for other materials. Among the possible sources, the smallness of the prism angle is the major factor that contributes to the error. Combined with the errors from other sources, the limit of accuracy in the measurement of n by the minimum deviation method is 1 to 2 parts in the third decimal place, a few times higher than that claimed by many workers.

The effect of impurities on the refractive index is considerable. In some cases, observations made on samples of questionable origin and undefined purity may yield radically different results. Simon [17] reported his radically different results (shown in figure 11) obtained for a germanium sample of high impurity content. Spitzer et al. [44] investigated the optical constants of heavily doped germanium with results greatly different from those of pure samples shown in figure 11. Thus, when the effects of impurities are taken into consideration, discrepancies from pure samples may be much higher than 2 parts in the third decimal place.

Although the error causing factors given above are well known, unfortunately they are not generally given in the literature and authors advance independent claims of their own precisions. In the present work it is assumed that data sets are concordant if they are not identical in the third decimal place.

More data can be found in references [41–58] and are given in tables A-5 and A-6, in which one can also find data sets obtained for thin films. No attempt was made to analyze the thin film data. However, it has been observed that the refractive indices of pure germanium thin films tend to agree with those of bulk crystal if the films are deposited on substrates maintained at elevated temperatures during the course of deposition or appropriately annealed after deposition. Surface contamination appears to be the most serious problem. However, data for thin films reported by those who exercised precaution in sample preparation are usually in agreement with those for bulk material.

Literature data on the temperature derivative of the refractive index of germanium is rather scarce. The data tabulated in tables A-7 and A-8 and plotted in figures 14 and 15 are mainly those of Lukes [36, 58, 59]. His dn/dT values were evaluated from his measurements of n given in table A-6 and figure 12.

Although considerable amounts of experimental data on the refractive index of germanium are available, they have received little analysis. The earliest quantitative results for germanium are generally attributed to Brattain and Briggs [41]. While they presented no dispersion relations in their work, they

noted that their results were extremely sensitive to specimen preparation and that large discrepancies arose between samples.

The first qualitative attempt was made by Rank et al. [35], who fitted a Cauchy type dispersion relation of the form

$$n = n_0 + \frac{a}{\lambda^2} + \frac{b}{\lambda^4},\tag{25}$$

where  $\lambda$  is in units of  $\mu$ m. They presented results for fits on both their own data and for the Brattain and Briggs data with the following constants:

Data	$n_1$	$a, \mu\mathrm{m}^2$	$b, \mu \mathrm{m}^2$
$RB\overline{C}$ [43]	$4.\ \overline{03}85$	$0.\overline{21345}$	$\overline{0.5363}$
BB [49]	3. <b>9992</b>	0.44647	0.6882

While this relation represented well each of the data sets, the authors found discrepancy between the two data sets as indicated by the coefficients.

The next dispersion relation was advanced by Hertzberger and Salzberg [31] which they developed using data for 13 materials in addition to germanium. They noted that comparisons of the data for 14 different materials indicated that all had refractive indices varying asymptotically with  $\lambda^2$ . They found the mean asymptote of all the materials in the UV region to be at  $\lambda_0 = 0.168~\mu m$ . Their dispersion relation is based upon a Taylor expansion in  $\lambda^2$  which retains only the linear terms. The form is

$$n = A + BL + CL^2 + D\lambda^2 + E\lambda^4, \tag{26}$$

where  $\lambda$  is in units of  $\mu m$ ,  $L=1/(\lambda^2-\lambda_0^2)$ , and the coefficients for the region 2.0 to 13.5  $\mu m$  are:

$$A=3.99931, \qquad D=-0.0000060, \\ B=0.391707, \qquad E=0.000000053. \\ C=0.163492,$$

These results agree very well with the data from which they are derived.

In the present work, eq (10) was used to represent the refractive index of germanium. The main task was the selection of the reliable data sets, the appropriate parameters  $\epsilon$  and  $\lambda_1$ , and the determination of the coefficients A and B. The data reported by Cardona et al. and Lukes were not used on the grounds that their values in our collection were read from the graphs in their papers. We have found that deviations between the graph readings and the true values were quite large, estimated at 1 to 2 percent. Values reported by Rank et al. (after correcting from vacuum values to air values) appear to be relatively too high compared with those of Briggs and Salzberg and Villa in the corresponding wavelength region, 2.0–2.4  $\mu$ m.

Although germanium has long been an important infrared material, its refractive index in the long wavelength region has not been well defined. Results from different workers often differ by as much as 0.003.

584 H. H. LI

Such a large discrepancy cannot be accounted for by merely experimental errors. Unknown impurities in some of the samples are probably responsible for the differences. However, this very important information is generally missing from the papers. As a result, the current knowledge of the refractive index of germanium still remains uncertain. Results of Edwin et al. [38] and Icenogle et al. [5] are uniformly higher than those of Salzberg and Villa [13] in the long wavelength region. Spitzer and I'an [44] observed that the refractive index of an impure sample in the long wavelength region is lower than that of a purer specimen. According to this, it would seem that Salzberg and Villa had more impurities in their specimen than did Edwin and Icenogle. This is not the case, however, as the above mentioned dala sets are essentially parallel in the long wavelength rigion while Spitzer and Fan's results indicate a progressively decreasing n with increasing wavelength (see figures 1 and 11). Based on this consideration, the selected data sets were given equal weight. Fortunately, data by Icenogle et al. cover a sizable tempere ture range, permitting the prediction of n at temperatures other than room temperature.

Selection of  $\vdots$  and  $\lambda_1$  presented some difficulties. Cardona et al. [3] observed the relative changes of refractive index  $\Delta n/n$ , at a wavelength of 3  $\mu$ m as temperature varied from 77 to 400 K with results plotted in figure 16. The average slope, (1/n)(dn/dT)of this plot is  $(6.9\pm0.4)\times10^{-5}$  K<sup>-1</sup>. Icenogle et al. obtained a higher value of  $9.9 \times 10^{-5} \text{K}^{-1}$  for (1/n)(dn/dT) in the varelength range 2.554 to 12.1  $\mu$ m. It appeared that din eq (10) could be determined from the relation  $(1/\epsilon)(d/\epsilon/dT) = (2/n)(dn/dT)$  using the value of (1/n)(dn/dT) at long wavelengths. The result would be an exponential relation of the form  $\epsilon = \epsilon_0 e^{\epsilon T}$ . However, the constant of (1/n)(dn/dT) does not hold for a wide temperature range. Hence, an empirical relation between  $\epsilon$  and T should be found based on available data of n.

It is shown in figure 12 that curves of temperature dependence of refractive index at various wavelengths are essentially parallel to each other and that each of them smoothly and monotonically increases with temperature. This provides a possibility to find a relation between  $\epsilon$  and T. As  $\epsilon$  closely equals  $n^2$  at long wavelengths, the best choice in the present case is the refractive indices at  $10.27 \mu m$  by Icenogle et al. [5]. However, their results cover only a temperature range from 100 to 298 K. A wider temperature coverage is required to establish it relation between  $\epsilon$  and T that is reliable over the temperature region 100-550 K of general interest. As shown in figure 12, the 5.156 µm curve of Lukes [36] is slightly above and parallel to the extension made from the 10.27 µm curve. The needed refractive indices at 10.27 µm in the higher temperature region was therefore obtained by appropriate extrapolation of "cenogle's data in that region.

In this way, the following polynomial equation is found to be valid at 10.27  $\mu$ m and over 100-550 K:

$$n^{2}(10.27 \ \mu\text{m}, T) = 15.3122 + 1.4571 \times 10^{-3}T + 3.5131 \times 10^{-6}T^{2} - 1.2089 \times 10^{-9}T^{3}.$$
 (27)

Since at long wavelengths the dielectric constant closely approaches but does not exactly equal  $n^2$ , it is therefore appropriate to consider the above quantity as a proportional factor and the dielectric constant is expressed as:

$$\epsilon(T) = En^2(10.27 \ \mu \text{m}, T),$$

where E is the proportional constant.

Spectral positions of natural absorption peaks in germanium have been studied by a number of investigators. McLean [2] investigated the absorption edge spectrum of germanium and found the optical energy gap at 300 K to be  $E_s = 0.663$  eV or  $\lambda_1 = 1.8703$  µm. Macfarlane et al. [8] further studied the absorption edge spectrum and found the temperature variation of the optical energy gap is essentially linear in the temperature range 200-300 K, but nonlinearity progressively predominates at lower temperatures as shown in figure 17. Lukes and Schmidt [9] studied the reflectivity spectrum of germanium and found two additional absorption peaks at λ<sub>2</sub>~0.589 μm and  $\lambda_3 \sim 0.282 \ \mu \text{m}$ . The latter corresponds to that predicted by Yu and Cardona [33]. As a summary of these findings, one now has three absorption peaks; namely:  $\lambda_1 = 1.8703 \ \mu \text{m}, \ \lambda_2 \sim 0.589 \ \mu \text{m}, \ \text{and} \ \lambda_3 \sim 0.282 \ \mu \text{m} \ \text{that}$ are supposed to have significant effects on the refractive index in the transparent region, 1.9-16 µm.

In this work, the selected data were fitted to an equation similar to eq (10) by including extra terms due to  $\lambda_2$  and  $\lambda_3$ . It was found, however, that introduction of the  $\lambda_2$  and  $\lambda_3$  terms did not improve the agreement obtained when only the  $\lambda_1$  term was included. Furthermore, the coefficients of the  $\lambda_2$  and  $\lambda_3$  terms could not be uniquely defined because there were no reliable data in the regions bounded by and near the three peak wavelengths. Also, the value of B was found to be negligibly low and hence the contribution of the last term in eq (10) was insignificant. As a consequence, eq (18) was adopted and the least squares fitting of selected data to this equation yielded the following expression for the refractive index of germanium in the ranges of 1.9 to 18  $\mu$ m and 100-550 K:

$$n^{2}(\lambda,T) = \epsilon(T) + \frac{L(T)}{\lambda^{2}} (A_{0} + A_{1}T + A_{2}T^{2}),$$
 (28)

where

```
 \begin{array}{l} \epsilon(T) \! = \! 15.2892 \! + \! 1.4549 \! \times \! 10^{-3} T \! + \! 3.5078 \! \times \! 10^{-6} T^2 \\ - 1.2071 \! \times \! 10^{-9} T^3, \\ L(T) \! = \! \mathrm{e}^{-3 \Delta L(T)/L_{208}}, \\ \lambda \! = \! \mathrm{wavelength} \  \, \mathrm{in} \  \, \mathrm{units} \  \, \mathrm{of} \  \, \mu\mathrm{m}, \\ T \! = \! \mathrm{temperature} \  \, \mathrm{in} \  \, \mathrm{units} \  \, \mathrm{of} \  \, \mathrm{K}, \\ A_0 \! = \! 2.5381, \\ A_1 \! = \! 1.8260 \! \times \! 10^{-3}, \\ A_3 \! = \! 2.8888 \! \times \! 10^{-6}, \end{array}
```

and from reference [60]

$$\begin{split} \frac{\Delta L(T)}{L_{293}} &= -0.089 + 2.626 \times 10^{-6} \, (T - 100) + 1.463 \\ &\times 10^{-8} (T - 100)^2 - 2.221 \times 10^{-11} \, (T - 100)^3 \\ &\qquad \qquad (100 < T < 293), \\ \frac{\Delta L(T)}{L_{293}} &= 5.790 \times 10^{-6} (T - 293) + 1.768 \\ &\times 10^{-9} (T - 293)^2 - 4.562 \times 10^{-13} (T - 293)^3 \\ &\qquad \qquad (293 < T < 1200). \end{split}$$

It is interesting to point out that the room temperature dielectric constant for germanium can now be calculated from the expression of  $\epsilon$  in eq (28). The result is 16.009 which is in good agreement with the commonly accepted value of 16.0.

Equation (28) was used to calculate the recommended values of the refractive index of germanium with uncertainties of  $\pm 2 \times 10^{-3}$ . The recommended values are given in table 4 and plotted in figure 18. To provide a visual comparision of the calculated values with experimental data, calculated values at a few specified temperatures and wavelengths are plotted in figures 12 and 13 where close agreement is revealed. Tables 5 and 6, respectively, give the calculated dn/dT and  $dn/d\lambda$  values based on the first derivatives of eq (28) with respect to T and  $\lambda$ . The corresponding plots are shown in figures 19 and 20.

Uncertainties in the calculated dn/dT values are estimated based on Icenogle's data [5] which are

essentially the basis for eq (28). Icenogle et al. evaluated  $\Delta n/\Delta T$  values using their own measurements of n and found the average uncertainty in  $\Delta n/\Delta T$  to be about  $\pm 0.5 \times 10^{-4} K^{-1}$ . Error bars corresponding to this amount are drawn on the calculated curves in figures 14 and 15 where calculated results are compared with experimental data. Although accuracies of experimental dn/dT are not available in Lukes' work [36, 38, 59], it is reasonable to use the same error bar as the experimental errors because the n versus T curves in figure 12 are closely parallel.

Uncertainties in the calculated  $dn/d\lambda$  are estimated from the expression:

$$\delta(du/d\lambda) \simeq \pm 2\delta n/\lambda$$

as discussed in subsection 3.1. Similar to the case of silicon, the uncertainties in  $dn/d\lambda$  of germanium are about  $\pm 5\times 10^{-4}\mu\text{m}^{-1}$  at 2.55  $\mu\text{m}$ ,  $1.2\times 10^{-4}\mu\text{m}^{-1}$  at 10  $\mu\text{m}$ , and  $0.7\times 10^{-4}\mu\text{m}^{-1}$  at 18  $\mu\text{m}$ .

It should be noted that calculated values in tables 4, 5, and 6 are given with more digits than warranted for the purpose of tabular smoothness.

As these values are calculated from an equation, it is desirable to give enough digits to show the variation of the variables in the equation and to provide comparasion among neighboring entries. To identify the unwarranted insignificant digits in the values, an overstrike is used. Appropriate uncertainties in the recommended values are discussed in the text and quoted in the footnotes of the tables.

# 4. Conclusions and Recommendations

Experimental data on the refractive index of crystalline silicon and germanium and its temperature derivative were exhaustively surveyed and reviewed. Values of physical properties which are related to the dispersion equation were selected from the open literature. In addition, a number of thin film data sets were also compiled.

The purpose of the present work was to survey and compile the available data and to generate recommended values of the refractive index and its temperature derivative for crystalline silicon and germanium. Recommended values for these materials were generated based on currently available data. Since the state of the refractive index of either of the crystals have not been well defined, our recommendations should be considered at best representing average values of the selected data sets. Many factors are known to influence the accuracy of the refractive index of a crystal. Although the minimum deviation method is known to be the most accurate way to determine the refractive index, this is not true in the case of silicon and germanium. Being highly refractive, the prism specimens used must be thin, usually about 15° apex angle or sometimes lower, thus giving rise to relatively higher uncertainties. Other possible sources of experimental errors were discussed by Primak [15]. However, the most important factor which contributes to the total error is the impurity content of the specimen. Although this is a well known source of error, unfortunately, this very important piece of information is usually not reported. As a consequence, discrepancies among the currently available data cannot be reasonably resolved.

Unless one is satisfied with the existing data having uncertainties of a few parts in the third decimal place, serious considerations should be given to obtaining data reliable in the fourth or fifth decimal place. A systematic measurement program on the refractive index should be carried out with the following considerations:

- 1. Experimental method. Because the minimum deviation method does not yield high accuracy in the case of Si and Ge, it is strongly felt that the interference method should be used. In this method, the determination of interference order plays the decisive role in the accuracy of the results. In order to obtain high accuracy, thick plate specimens should be used.
- 2. Sample characterization. As the impurity content of the sample strongly affect the refractive index, the impurities in the sample should be ascertained and reported. Merely reporting the electrical resistivity of the sample is not adequate. The nature and amount of impurities should specifically be reported. In order to see the effects of impurities on the refractive index, measurement should be carried out for a group of specimens with systematically controlled impurities.
  - 3. Environmental control. Since both silicon and

germanium have high temperature coefficients of refractive index (in the order of  $10^{-4} \mathrm{K}^{-1}$ ), the temperature of the sample has to be carefully controlled in order to achieve the required accuracy. Pressure has little effect on the refractive index under ordinary conditions. The pressure coefficient of the refractive index of Ge at 297 K is  $(1/n)(dn/dP = -7 \pm 2 \times 10^{-7} \mathrm{kg}^{-1} \mathrm{cm}^2$  [3]. That of Si is  $-3 \pm 2 \times 10^{-7} \mathrm{kg}^{-1} \mathrm{cm}^2$  [3].

In conclusion, it should be emphasized that the present work does not resolve the discrepancies between the available data sets, it simply recommends the most probale values of the refractive index that a pure crystal of Si and Ge may have with the quoted uncertainties. Also, it should be noted that, as in any statistical study of this type, the dispersion equations, eqs (22) and (28), are valid to the reported accuracy only within the region of experimental data. In general, extrapolation of these equations for use outside of this region is invalid for quantitative results. Finally, the type of analysis presented here assumes the data to be an absolutely correct representation of the model at hand, which is not generally true since the model is an oversimplification of the true dispersion relation. However, for predictive purposes, based upon the experimental data from several authors, and within the usable region of the data, we believe that these equations are valid for calculation of the refractive index in the given wavelength and temperature regions.

### **Appendix**

The tables included in the Appendix are available experimental data compiled during the course of present work. The collected information covers the reported works in the last three decades from 1949 to 1978.

The tables give for each set of data the following information: the reference number, author's name (or names), year of publication, wavelength range, temperature range, the description and characterization of the specimen, and information on measurement conditions contained in the original paper.

TABLE A-1. EXPERIMENTAL DATA ON THE REFRACTIVE INDEX OF SILICON (Wavelength Dependence)  $[ \mbox{Temperature, T, K; Wavelength, } \lambda, \mbox{$\mu m$; Refractive Index, n} ]$

TABLE A-5. EXPERIMENTAL DATA ON THE REFRACTIVE INDEX OF GERMANIUM (Wavelength Dependence) (continued)

Data Set [Ref.]	λ	n	Specifications and Remarks	Author(s), Year
32(cont.)	1.901	4.192	$\rho$ = 50 Ω-cm; index of refraction	Kornfeld, M.I., 1960
[48]	2.000	4.174	measured by deviation method; data	ı
	2.098	4.159	taken from a figure.	
	2.210	4.148		
33		50 K)	High purity germanium; prism cut from	Kornfeld, 4.1., 1960
[48]	1.901	4.230	a single crystal; prism angle: 4°21'30";	·
	1.993	4.212	$\rho$ = 50 $\Omega$ -cm; index of refraction mea-	
	2.098 2.218	4.197 4.184	sured by deviation method; data taken from a figure.	
34	(T=29	98 K)	Thin films of germanium obtained by	Lukes, F., 1960
[37]	0.358	4.001	evaporating very pure germanium in a	,, <sub>-</sub>
-	0.377	4.022	vacuum from molybdenum or tungsten boats	
	0.402	3.880	on to glass plates at a pressure on the	
	0.431	3.717	order of 10 <sup>-5</sup> mmHg; refractive indices	
	0.471	3.616	determined from the measured values of	
	0.522	4.148	the transmissivity and reflectivity;	
	0.604	4.905	data taken from a figure.	
	0.648	4.987		
	0.656	5.008		
	0.677	4.927		
	0.802	4.787		
35		98 K)	Thin films of germanium obtained by	Lukes, F., 1950
[37]	0.827	4.95	evaporating very pure germanium in a	
	0.836	5.01	vacuum from a molybdenum or tungsten	
•	0.875	4.45	boats on to glass plates at a pressure	
	0.904	4.50	on the order of 10 <sup>-5</sup> mmHg; refractive	
	0.970	4.88	indices determined from the measured	
	0.973 0.983	4.85 4.82	values of the transmissivity and re-	
	1.00	4.55	flectivity; data taken from a figure.	
	1.04	4.69		
	1.20	4.23		
	1.44	4.15		
	1.50	4.00		
	2.21	3.96		
36	(T=29	8 K)	Single crystal; polished specimens of	Kiseleva, N.K. and
[49]	0.43	4.22	$7 \times 7 \text{ mm}^2$ surface; refractive index	Pribytkova, N.N.,
	0.46	4.14	determined from the reflectance data	1961
	0.49	4.10	from the specimen measured in air and	
	0.52	4.06	in an immersing liquid of known refrac-	
	0.54	4.18	tive index; data taken from a figure.	
	0.58	4.42		
	0.60	4.70		
	0.62	4.74		
	0.64	4.74		
	0.66	4.54		
	0.68	4.26		
	0.70	4.15		
	0.73 0.76	4.07 3.99		
37	(T=2	298 K)	Calculated data based upon similarities	Hertzberger, M. and
				Salzberg, C.D., 1962
[31]	2.0	4.1083	in several materials; data taken from	Data Chertiff Armed 1504

J. Phys. Chem. Ref. Data, Vol. 9, No. 3, 1980
